Key words: gender, quality of life, social functioning, opioid, HIV.

Summary
Abstract. The objective of the study was to explore clinical, psychological and social characteristics of female injectable opioid users (FIOUs) with different HIV status living in Republic of Belarus.

Materials and methods. A cohort of 217 FIOUs were examined (104 HIV-positive and 113 HIV-negative patients. To assess patient social functioning, quality of life, and craving for narcotic substances the Scale of social functioning, SF-36 and Scale of drugs craving were used.

Results. The majority of patients had frequent change of employment place and reported absence from work (25.9% in HIV-positive group and 26.5% in HIV-negative group; P>0.05). HIV-positive patients reported low professional qualification and education level significantly more often than HIV-negative patients (20.1% vs 13.2%, p<0.05, and 43.3% vs. 36.2%, p<0.05, respectively). They also characterized family climate as “hostile” more often (80.7% vs. 61.0%, p<0.05). Both groups reported high rates of parental alcohol abuse (17.3% in HIV-positive and 14.1% in HIV-negative individuals, p>0.05), and of parental divorces (23.1% and 28.3%, p>0.05, respectively). Conclusion. Female injectable opioid users have marked social disfunction involving social and professional domains. Specific needs of this group of mental healthcare users need to be addressed.

Introduction
Females represent one third of injectable drug users population worldwide, and nearly 0.11% of female population inject psychotropic substances [5].

Women consume opioids more often than men [1]. It is also known that women are more likely to misuse the prescribed psychotropic drugs [2; 3].

Risk factors for drug abuse among women are sexual abuse in childhood and domestic violence. Nearly 20% of women who previously have experienced violence develop a mental disorder, most often depression and post-traumatic stress disorder [6]. Despite the fact that women start using narcotic drugs later than men, consumption of cannabis, opioids and cocaine is growing faster in this population than in men, before developing disorders on the basis of receiving surfactant, compared with men, women who use heroin, at least use it with the help of injections in smaller doses and for a short time, are younger, and are often influenced by drug-using sexual partners, who often do the first injection of drugs to a woman [6].

The transition to IPRs among women may be due to personal characteristics or external circumstances. This may be a consequence of problems in personal life, affective and anxiety disorders, desire to lose weight, struggle with exhaustion, anesthesia, self-treatment of mental disorders, physical or sexual violence experienced in childhood, involvement in the sex industry and communication with injecting drug users (IDUs) [6].

Many more often than not, women who practice pit report using needles in combination, explain that they are not aware of the risks involved, are unable to buy syringes/needles from pharmacies, or fear of over-policing, using shared needles as a sign of love or trust in a partner. “Dirty” injections can cause damage to the veins and cause serious complications. FIOU are experiencing problems such as fatigue, loss of weight, withdrawal symptoms of pain, depression and a su-
icide attempt, many of them suffer from sexually transmitted diseases, viral hepatitis. For these women, access to health care is mainly hampered by the fact that society condemns women who inject drugs more than men [6].

Women heroin users, younger age compared with men who rarely consume it by injection in smaller doses and for a shorter time, often under the influence of sexual partners, using drugs that often make the woman the first injection of drugs. Often the transition to injecting drug use (IDU) among women is due to personal characteristics of women or external circumstances due to problems in their personal lives, affective or anxiety disorders, desire to lose weight, fight against exhaustion, anesthesia, self-treatment of mental disorders, physical and sexual violence experienced in childhood, involvement in the sex industry or communication with IDUs [1].

Many women who practice pit report sharing needles, either because they are not aware of the risks, or because they are unable to buy needles from pharmacies, or because they fear the police, or because they share needles as a sign of love or trust in their partner. Lack of IDU experience can lead to vein damage and cause serious complications. FIOU often experience fatigue, weight loss, pains, depression, suicide attempt, many of them suffer from sexually transmitted diseases, hepatitis. Access to health care for them is difficult because of the public condemnation [1].

For the period between 1999 and 2010, mortality among FIOU, in particular the use of opioid analgesics prescription in the USA increased five-fold among men by 3.6 times. More than 15,000 women died from a drug overdose in the United States in 2012. From 2007 to 2008 in England and Northern Ireland, overdose mortality among women increased by 17%, among men by 8% [3].

The purpose of this study is to study the medical and social characteristics of HIV-positive (HPW) and HIV-negative (HNW) women who inject drugs (opioid group) (FIOU).

Materials and methods of research
This study was conducted on the basis of Grodno State Medical University according to the research program “To develop the criteria for clinical and social functioning, to assess the quality of life and dis-adaptation of injecting drug users (IDUs) on different stages of HIV infection” (No State Registration 201501548), with the scientific and methodological support of the National Research Center for Addiction Problems – a branch of the National Medical Research Center of Psychiatry and Narcology named after V. P. Serbsky Ministry of Health of Russia.

The study design had combined elements of both cross-sectional and longitudinal analyses. A 6-fold assessment of the monitored parameters was performed before and after treatment, – after 1, 3, 6 and 12 months from the beginning of follow-up.

The clinical study was performed in accordance with GCP rules, according to the Protocol using an individual registration data card. There were examined 217 female psychiatric inpatients with opioid dependence living in the Republic of Belarus. The examined individuals were randomized into 2 groups: group 1 – 104 HPW with the average age of 30.8 (SD=4.86) and group 2 – 113 HNW with the average age of 29.9 (SD=6.67).

Results and discussion
The majority of FIOU such as the lack of a stable employment. As well, 17.3% of HPW and 20/17.6% HNW currently held a temporary or seasonal job; frequent changes of places of work, absence from work were observed in 27/25.9% of HPW and 30/26.5% HNW; not working, not studying, avoid employment 63/60.5% HPW and 53/46.9% HNW; were employed in low-skilled jobs 24/23.1% of HPW and 19/16.8% of HNW. Systematic violations of labor discipline in 16/15.3% HPW and 9/7.9% HNW were shown in the form of frequent layoffs; in 15/14.4% HPW and 9/7.9% HNW – administrative penalties; in 19/18.2% HPW and 16/14.1% HNW – conflict relations /negative attitude to work. Disability had 3/2.88% of HPW and 1/0.88% of HNW.

Without a profession were 45/43.2% HPW and 38/33.6% HNW, workers 55/52.8% HPW and 52/46.0% HNW, employees – 6/5.7% HPW and 22/19.4% HNW. Low educational level (incomplete secondary education) was characteristic for 21/20.1% HPW and 15/13.2% HNW, secondary education – 43/41.3% HPW and 41/36.2% HNW, secondary special education – 36/34.6% HPW and 43/38.0% HNW.

Their own families had 49/47.1% of HPW and 48/42.4% of HNW. Were in primary marriage 31/29.8% HPW and 37/32.7% HNW, repeated – 13/12.5% HPW and 14/12/3.0% HNW, civil – 18/17.3% HPW and 19/16.8% HNW. Divorced were 20/19.2% HPW and 24/21.2% HNW. Had children 72/69.2% HPW and 73/64.6% HNW. Lived with own family 31/29.8% HPW and 37/32.7% HNW. Most of the time was spent among unfamiliar people, came home only for the night 21/20.1% of HPW and 9/7.6% of HNW (p<0.05).

The situation in the family was characterized by often conflicts in 84/80.7% of HPW and 69/61.0% of HNW, alcohol abuse of parent(s) – 18/17.3% of HPW and 16/14.1% of HNW, lack of sufficient financial resources, low family income– 57/54.8% of HPW and 45/39.8%; of HNW (p<0.05), divorce of parents – 24/23.1% of HPW and 32/28.3% of HNW.

Age of the first drug trial was 18.1 (SD=3.4) among
HPV and 20.4 (SD=4.8) among HNV. The main way the drug is taken at 84/80.7% of HPW and 103/91.1% HNW was only injecting. The combination of different methods of administration of drugs was mentioned by 9/8.6% of HPN and 1/0.8% of HNW (p<0.01). At the same time, non-disposable syringes/needles were used by 46/44.2% of HPW and 11/9.7% of HNW (p<0.001), ignoring the sterility of the drug or the container in which it was 68/65.3% of HPW and 53/46.9% of HNW (p<0.05).

The leading motive of drug abuse in 21/20.1% of HPW and 31/27.4% of HNW was the search for new pleasant sensations and curiosity. The desire to facilitate contact with people, to satisfy sexual needs were reported by 10/9.6% of HPW and 9/7.9% HNW, to show his independence – 22/21.1% HPW and 35/30.9% HNW, induce euphoria, an altered state of consciousness – 41/39.4% of HPW and 49/43.3% (HNW), the desire to neutralize the negative emotional experiences – 24/23.1% of HPW and 27/23.8% HNW, to reduce apathy, to improve working productivity – 26/25.0% HPW and 33/29.2% HNW to mitigate the withdrawal state – 86/82.6% of HPW and 68/60.1% HNW (p<0.05); to protest – 5/4.8% HPW and 5/4.4% HNW.

The use of drug while being alone was reported by 17/16.3% HPW and 11/9.7% HNW (p<0.05), in the criminalized company – 83/79.8% HPW and 89/78.7% HNW. If it is impossible to get the “main” drug, used other psychoactive substances (PAS) 41/39.4% HPW and 41/36.2% HNW, in combination with alcohol or drugs used drugs 44/42.3% HPW and 39/34.5% HNW, a few PAS with the presence of the preferred drug – 3/2.8% HPW and 11/9.7% HNW (p<0.05).

The duration of drug use without dependence from 31/29.8% of HPW and 28/24.7% of HNW up to 1 month up to 2 months – 11/10.5% of HPW and 16/14.1% HNW, 3 months – 1/0.9% of HPW and 5/4.4% HNW (p<0.05), 6 months – 41/39.4% of HPW and 40/35.3% HNW, more than 6 months – 13/12.5% of HPW and 21/18.5% HNW. The emergence of signs of a withdrawal state from the beginning of the drug up to 1 month recorded at 35/33.6% of HPW and 25/22.1% HNW, up to 2-3 months – 17/16.3% of HPW and 22/19.4% HNW, up to 6 months – 41/39.4% of HPW and 40/35.3% HNW, more than 6 months – 16/15.3% of HPW and 24/21.2% HNW. Illegal drug use in 62/59.6% of HPW and 34/30.0% HNW accounted for more than 10 years; 5-10 years – 30/28.8% of HPW and 38/33.6% HNW, less than 5 year – 7/6.7% of HPW and 22/19.4% of HNW (p<0.01).

The main motive for the break in drug use in 32/30.7% of HPW and 26/23.0% of HNW was the desire to reduce the dose of the drug; in 38/36.5% of HPW and 57/50.4% of HNW(p<0.05) – the desire to completely abandon drug use, in 62/59.6% of HPW and 61/53.9% of HNW – financial difficulties associated with the acquisition of the drug; 42/40.3% of HPW and 37/32.7% of HNW – forced abstinence; in 49/47.1% of HPW and 37/32.7% HNW – no permanent source of drug; in 26/25.0% of HPW and 40/35.3% of HNW – moral pressure of relatives.

Attraction to drug use at 33/31.7% HPW and 60/53.1% HNW was situational, when released into the environment; 16/15.3% HPW – situational due to the “double stigma – HIV-infected female drug addicts”; 42/40.3% of HPW and 55/48.6% HNW – obsessive, escalating of conflict; 68/65.3% HPW and 42/37.1% HNW (p<0.05) – compulsive search of the drug or its substitutes, desire for contacts with the IDUs to obtain the illegal drug; 16/15.3% of HPW and 16/14.1% HNW – compulsive with a pronounced behavioral component with internal tension, excitability and increased irritability.

More than 10 cases of withdrawal states were observed in 37/35.5% of HPW and in 23/20.3% HNW; up to 10 of such cases were observed in 30/28.8% of HPW and in 34/30.0% of HNW; up to 5 cases – in 25/24.0% HPW and 33/29.2% HNW, once – in 8/7.6% HPW and 10/8.8% HNW. The duration of withdrawal status in 5/4.8% HPW was more than 14 days, 14 days in 15/14.4% HPW and 1/0.8% HNW (p<0.01), 10 days – 36/34.6% HPW and 72/33.8% HNW (p<0.05), 7 days – 40/38.4% HPW and 62/54.8% HNW, 3-5 days – 3/2.8% HPW and 6/5.3% HNW. The severity of withdrawal state was mild in 3/2.8% of HPW and 10/8.8% of HNW (p<0.05); 79/75.9% of HPW and 77/68.1% of HNW – moderate and in 18/17.3% of HPW and 13/11.5% of HNW – severe. The most common manifestations of a withdrawal state in 82/78.8% of HPW and 76/67.2% HNW were somatic and neuro-vegetative disorders, tremor, sweating, disorders of the cardiovascular system; in 7/6.7% of HPW and 22/19.4% HNW (p<0.05) – psychopathological disorders (fear, anxiety, depression, agitation); in 22/21.1% of HPW and 29/25.6% HNW – pain, convulsive disorders, 22/21.1% of HPW and 17/15.0% HNW – asthenic syndrome (sleep disturbances, general weakness, malaise).

The predominant symptoms in post-abstinent state were asthenic with general weakness, malaise, nausea, dizziness, observed in 70/67.3% of HPW and 78/69.0% of HNW; in 28/26.9% of HPW and 20/17.6% of HNW were dominated by behavioral disorders; in 21/20.1% of HPW and 15/13.2% of HNW – aspontaneity. The duration of post-abstinent state was in 15/14.4% HPW and 5/4.4% HPW more than 1 month; in 67/64.4% HPW and 62/54.8% HNW – up to 1 month; in 17/16.3% HPW and 13/11.5% HNW – 14 days; in 4/3.8% HPW and 20/17.6% HNW – 3-7 days (p<0.01)

The main type of intoxication experience in 65/62.5%
of HPW and 61/53.9% of HNW was “pleasant relaxation”, feelings of peace, deep self-contemplation; in 34/32.6% of HPW and 48/42.4% of HNW – desire for activity, feeling of fullness of life; in 50/48.0% of HPW and 54/47.7% of HNW – euphoria, emotional excitement, elation. However, modified forms of drug intoxication were also observed such as predominance of low mood, sadness at 18/17.3% of HPW; dysphoria and irritability – 4/3.8% of HPW; aggressiveness on the background of emotional arousal – in 5/4.8% HPW vs 1/0.8% HNW (p<0.05); demonstrative suicidality – in 2/1.9% of HPW; losing the sense of tact and shame, tearfulness – in 5/4.8% of HPW vs 1/0.8% of HNW (p<0.05).

A complete abstinence from drug use was observed in 14/13.5% of HPW and 8/7.1% of HNW, partial – in 58/55.8% of HPW and 45/39.8% of HNW (p<0.05), spontaneous – in 8/7.7% of HPW and 3/2.7% of HNW (p<0.05); therapeutic remission – in 20/19.2% of HPW vs 26/23.0% of HNW. Early relapse (within 1 month after treatment) was observed in 40/38.5% HPW and 35/31.0% HNW, up to 3 months – in 18/17.3% HPW vs 13/11.5% HNW; 6 months – 7/6.7% HPW vs 21/18.6% HNW (p<0.05); up to 12 months-24/23.1% HPW vs 17/15.0% HNW; more than 12 months – 12/11.5% HPW vs 17/15.0% HNW.

The predominant symptoms in 70/67.3% of HPW and 78/69.0% of HNW in post-abstinent state were asthenic with general weakness, malaise, nausea, dizziness; in 28/26.9% of HPW and 20/17.6% of HNW – active continuation, due to despair, drug use and social isolation; 19/18.3% HPW – fatigue from the forced use of documents, difficulty of access to health care; 25/24.0% HPW – poor hygiene, malnutrition; 21/20.2% of HPW – loss of job loss, unemployment, frequent change of employment; 64/61.5% HPW – increased risk of job loss, unemployment, frequent change of employment place; 80/76.9% of HPW – housing and financial problems, debts; 26/25.0% of HPW – lack of housing or registration at the place of residence, semi-legal residence; 35/33.7% of HPW – poor hygiene, malnutrition; 21/20.2% of HPW – loss of documents, difficulty of access to health care; 25/24.0% of HPW – side effects of highly active antiretroviral therapy; 3/2.9% HPW – a sense of “strange medicinal smell” from one’s own body, aversion to one’s own body; 6/5.8% HPW held ineffective antiviral therapy; 4/3.8% of HPW the appearance of visible defects in appearance.

Among HPW, 37/35.6% maintained the ability to per-
form their daily household, social and professional duties, 58/55.8% of HPW experienced difficulties with these duties, and 10/9.6% of HPW failed to perform these duties.

Conclusions

The majority of females who inject opioids have high level of social dysfunction, reporting failure to perform domestic, social and professional duties. In in FIOU with HIV-positive status these problems are more pronounced.
